Multi-signal

Multi-information

Exploiting new physical events/signals combinations

The multisignal
approach in the STEM

- ▶ Pushing the limits of the existing spectroscopic techniques
- ▶ Inventing new spectroscopies

Quelles performances actuelles en microscopie électronique en transmission?

- Résolution spatiale (correcteurs d'aberrations de la lentille objectif)
- Résolution énergétique (monochromateurs)
- Convergence photons/électrons

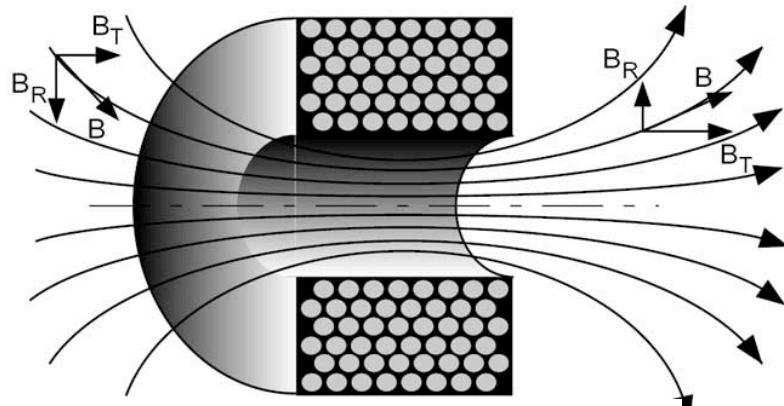

Pour quelles applications?

Recent advances in spatial resolution

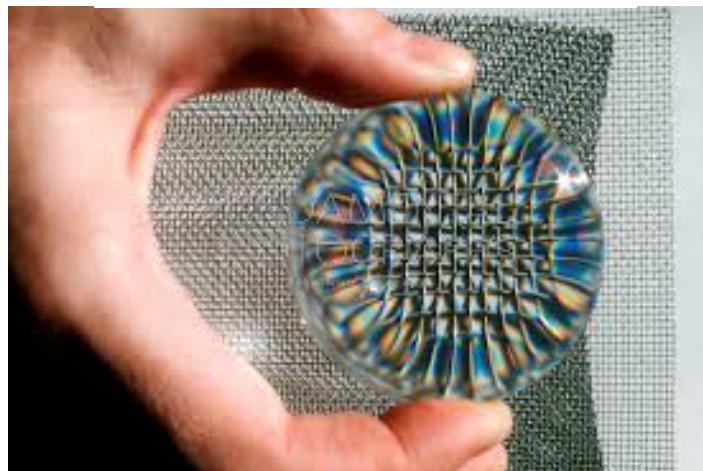

- Electron aberration correctors
- New possibilities in imaging

Imaging down to the atomic scale

$$\lambda (100 \text{ keV}) = h/p = 3 \text{ pm}$$

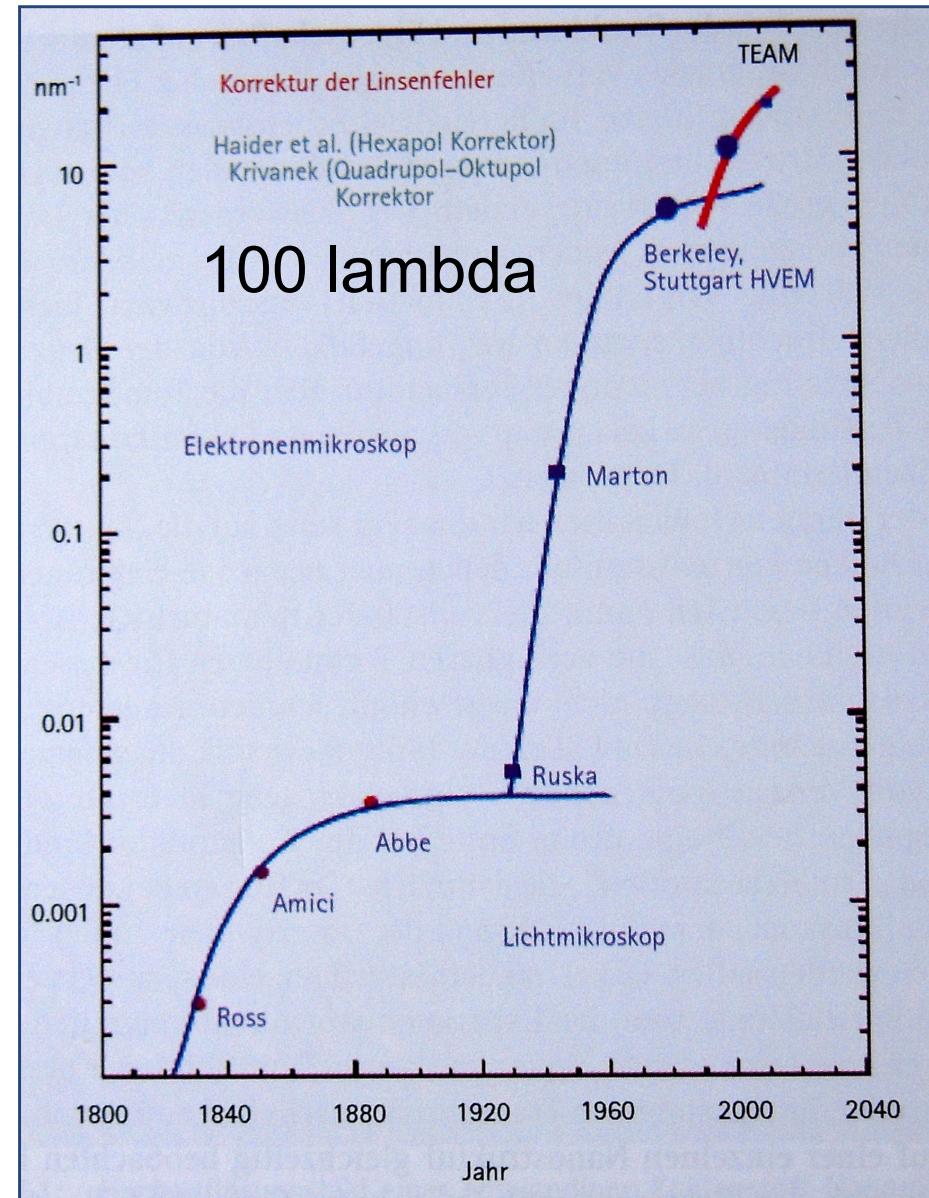

$$d_o = 0.61 \lambda / \alpha_o$$

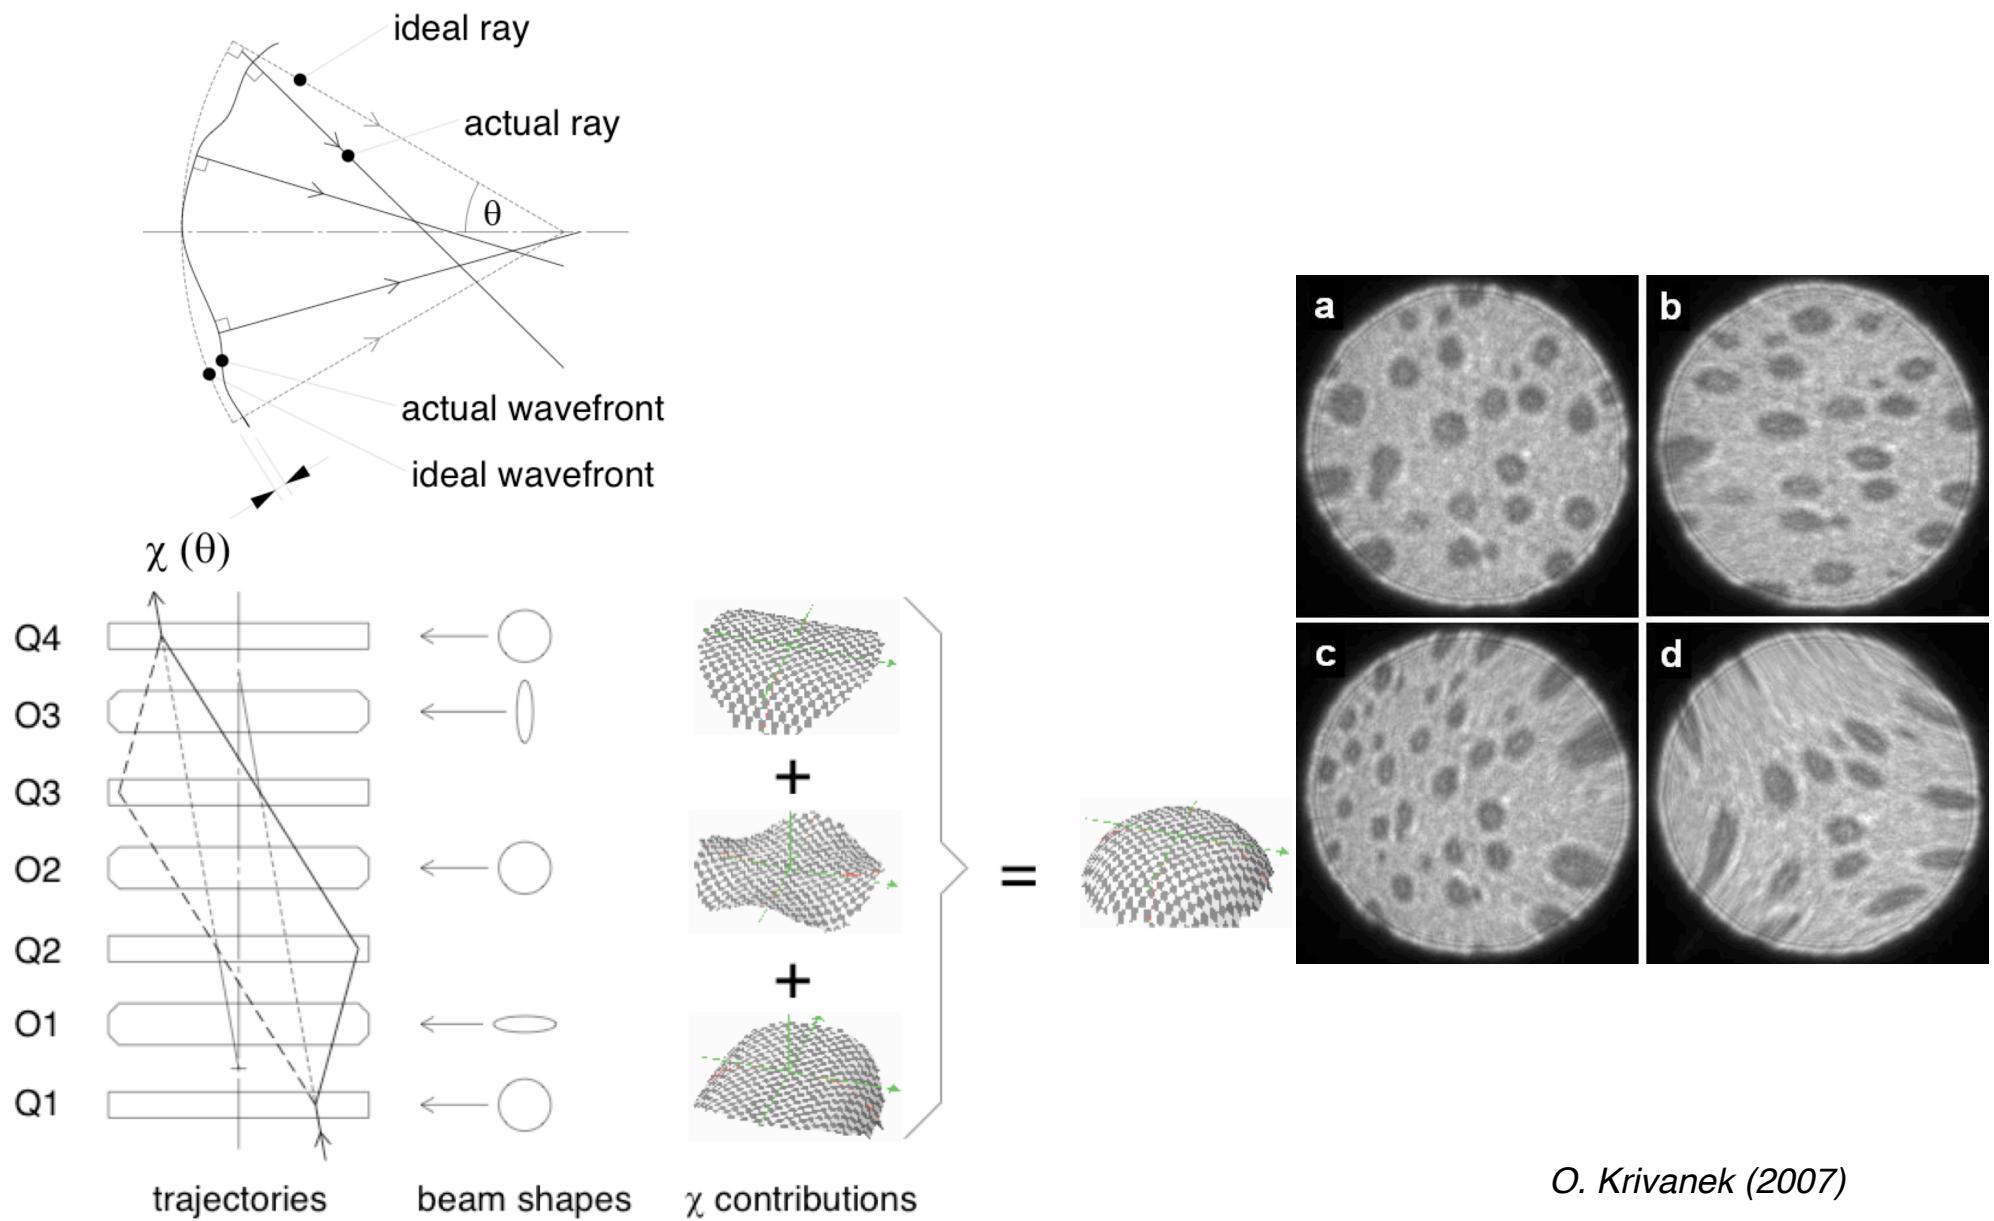

$$d \sim 1.5 \text{ \AA} = 50 \lambda$$

20 lambda = 60 pm

Recent advances in energy (spectral) resolution

- New generation monochromators/
energy resolution and stability
 - New application range

Electron Monochromators: two strategies

- Monochromator working with **high energy electron (100keV)** (native dispersion is weak so a lot of optical element/quad to increase the dispersion; ground, no space charge, analyzer can be quite symmetric with mono), Krivanek et al.
- Monochromator working with **low energy electron (1keV)** (higher dispersion, low aberration, integrated in the gun), For example Wien filter from Mook and Kruit, UM (2000) 129-139.
Drawbacks: « Boersch » effect/low intensity, selected energy dependent from HT

Nion high energy-resolution monochromator

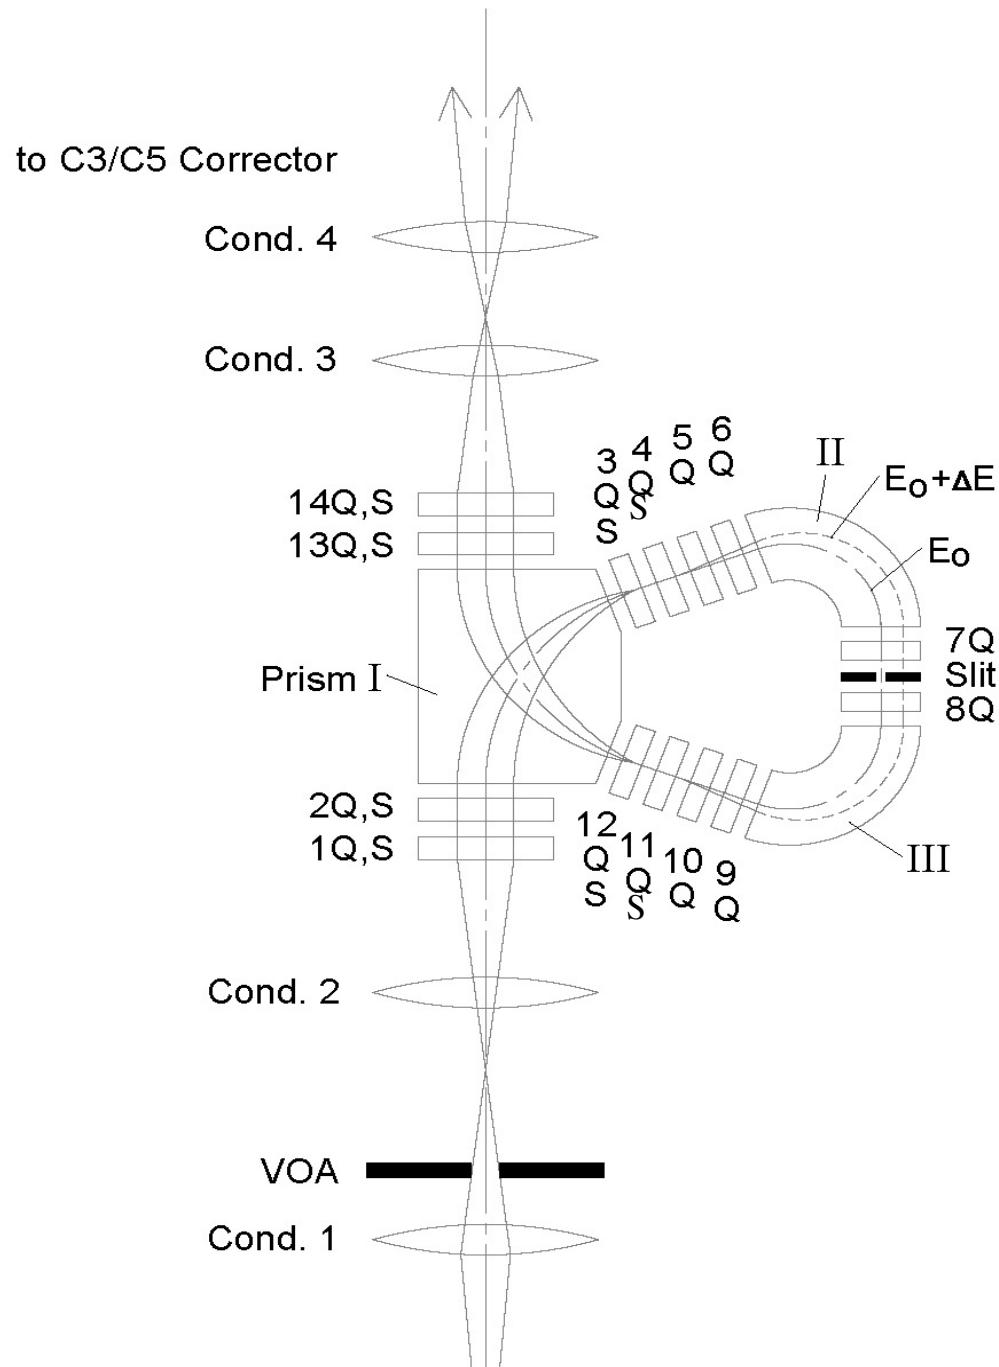

Figure shows Nion's design of a dispersing-undispersing monochromator operating on 20-200 kV electrons.

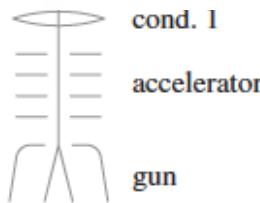

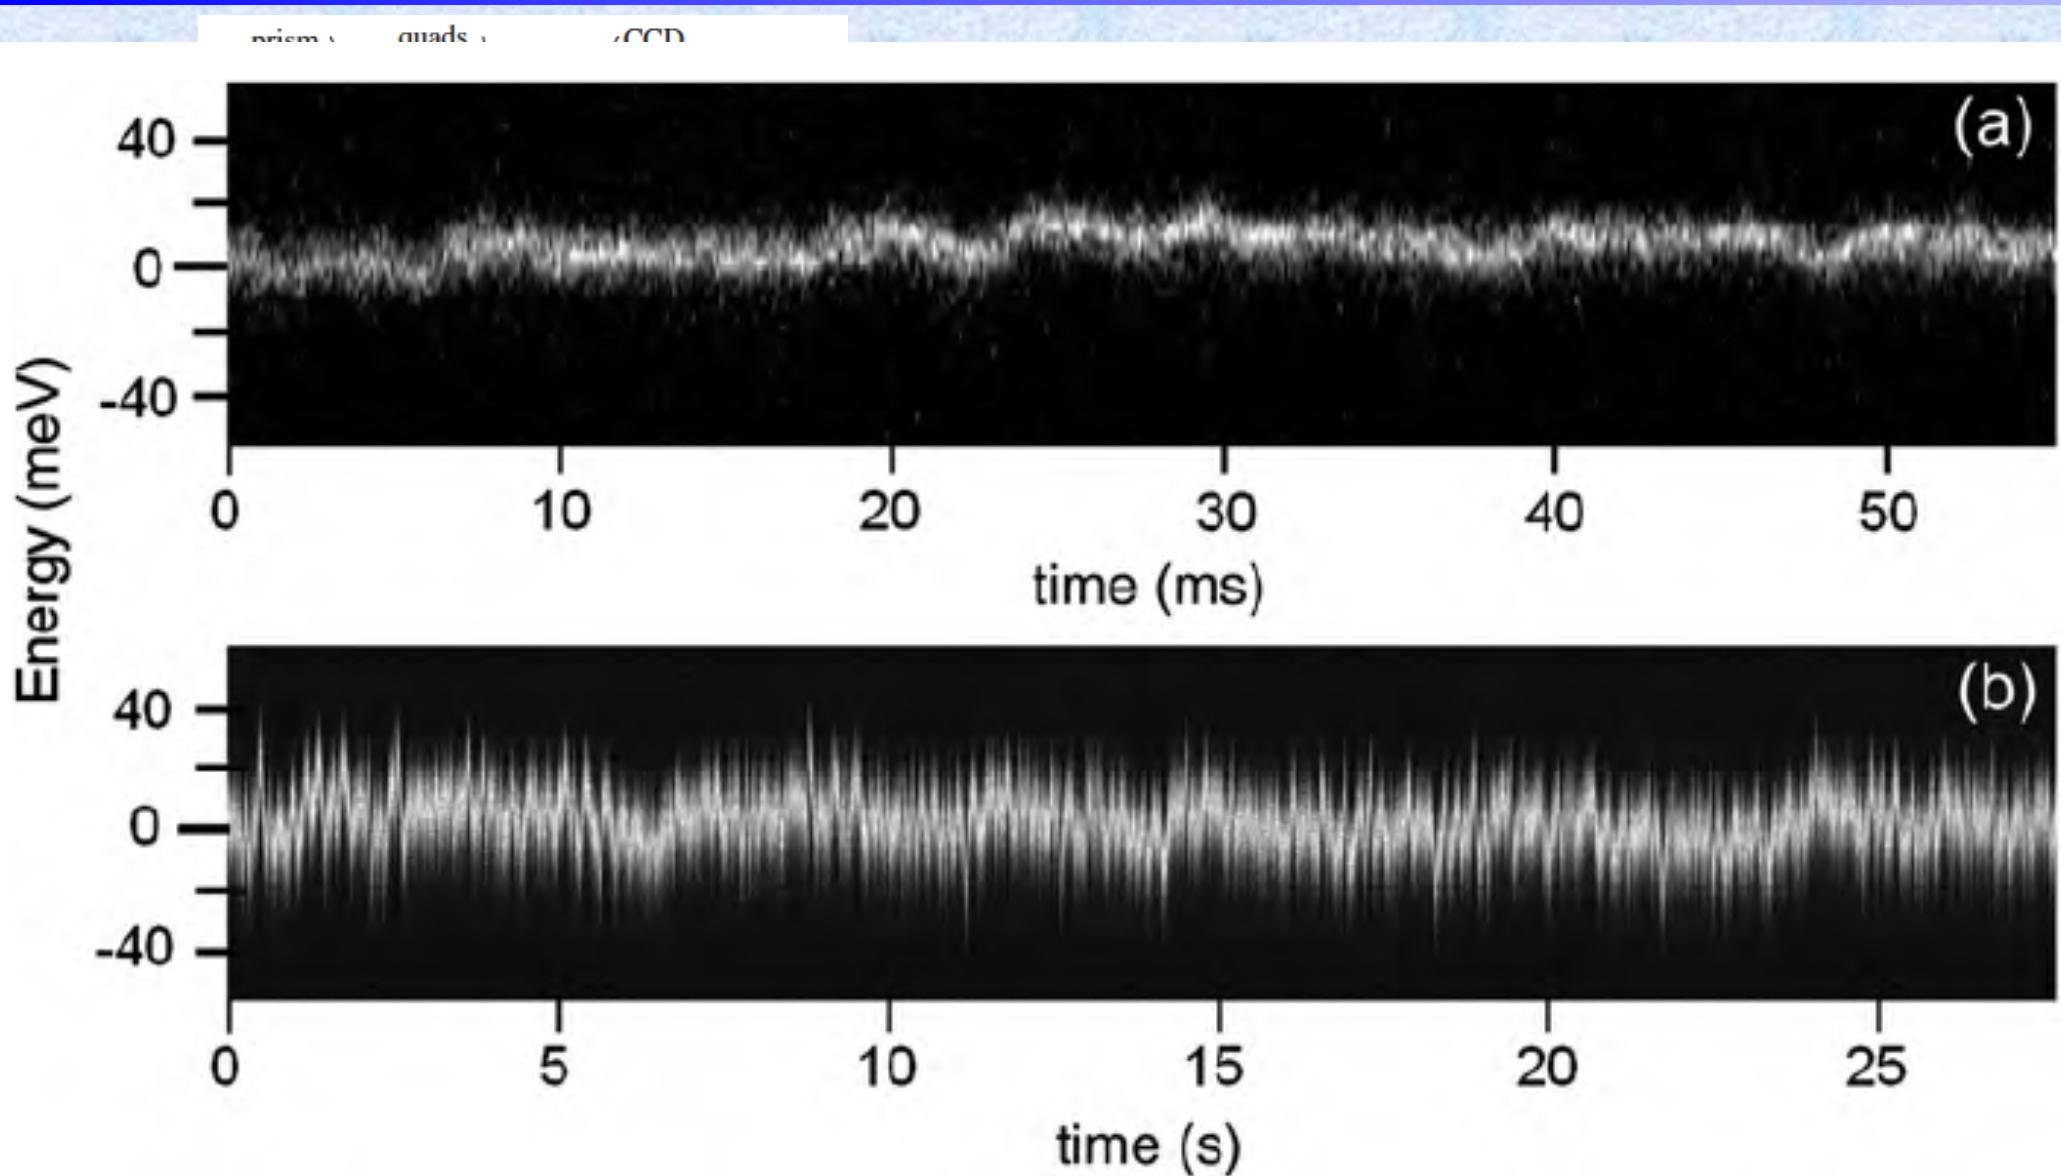

Spectrum is magnified at the slit. The spectrum is demagnified and the dispersion is canceled by the second half of the monochromator.

~ 30 meV energy resolution should be possible soon, better in the long term.

Now being built at Nion, for Arizona State U. and Rutgers U.

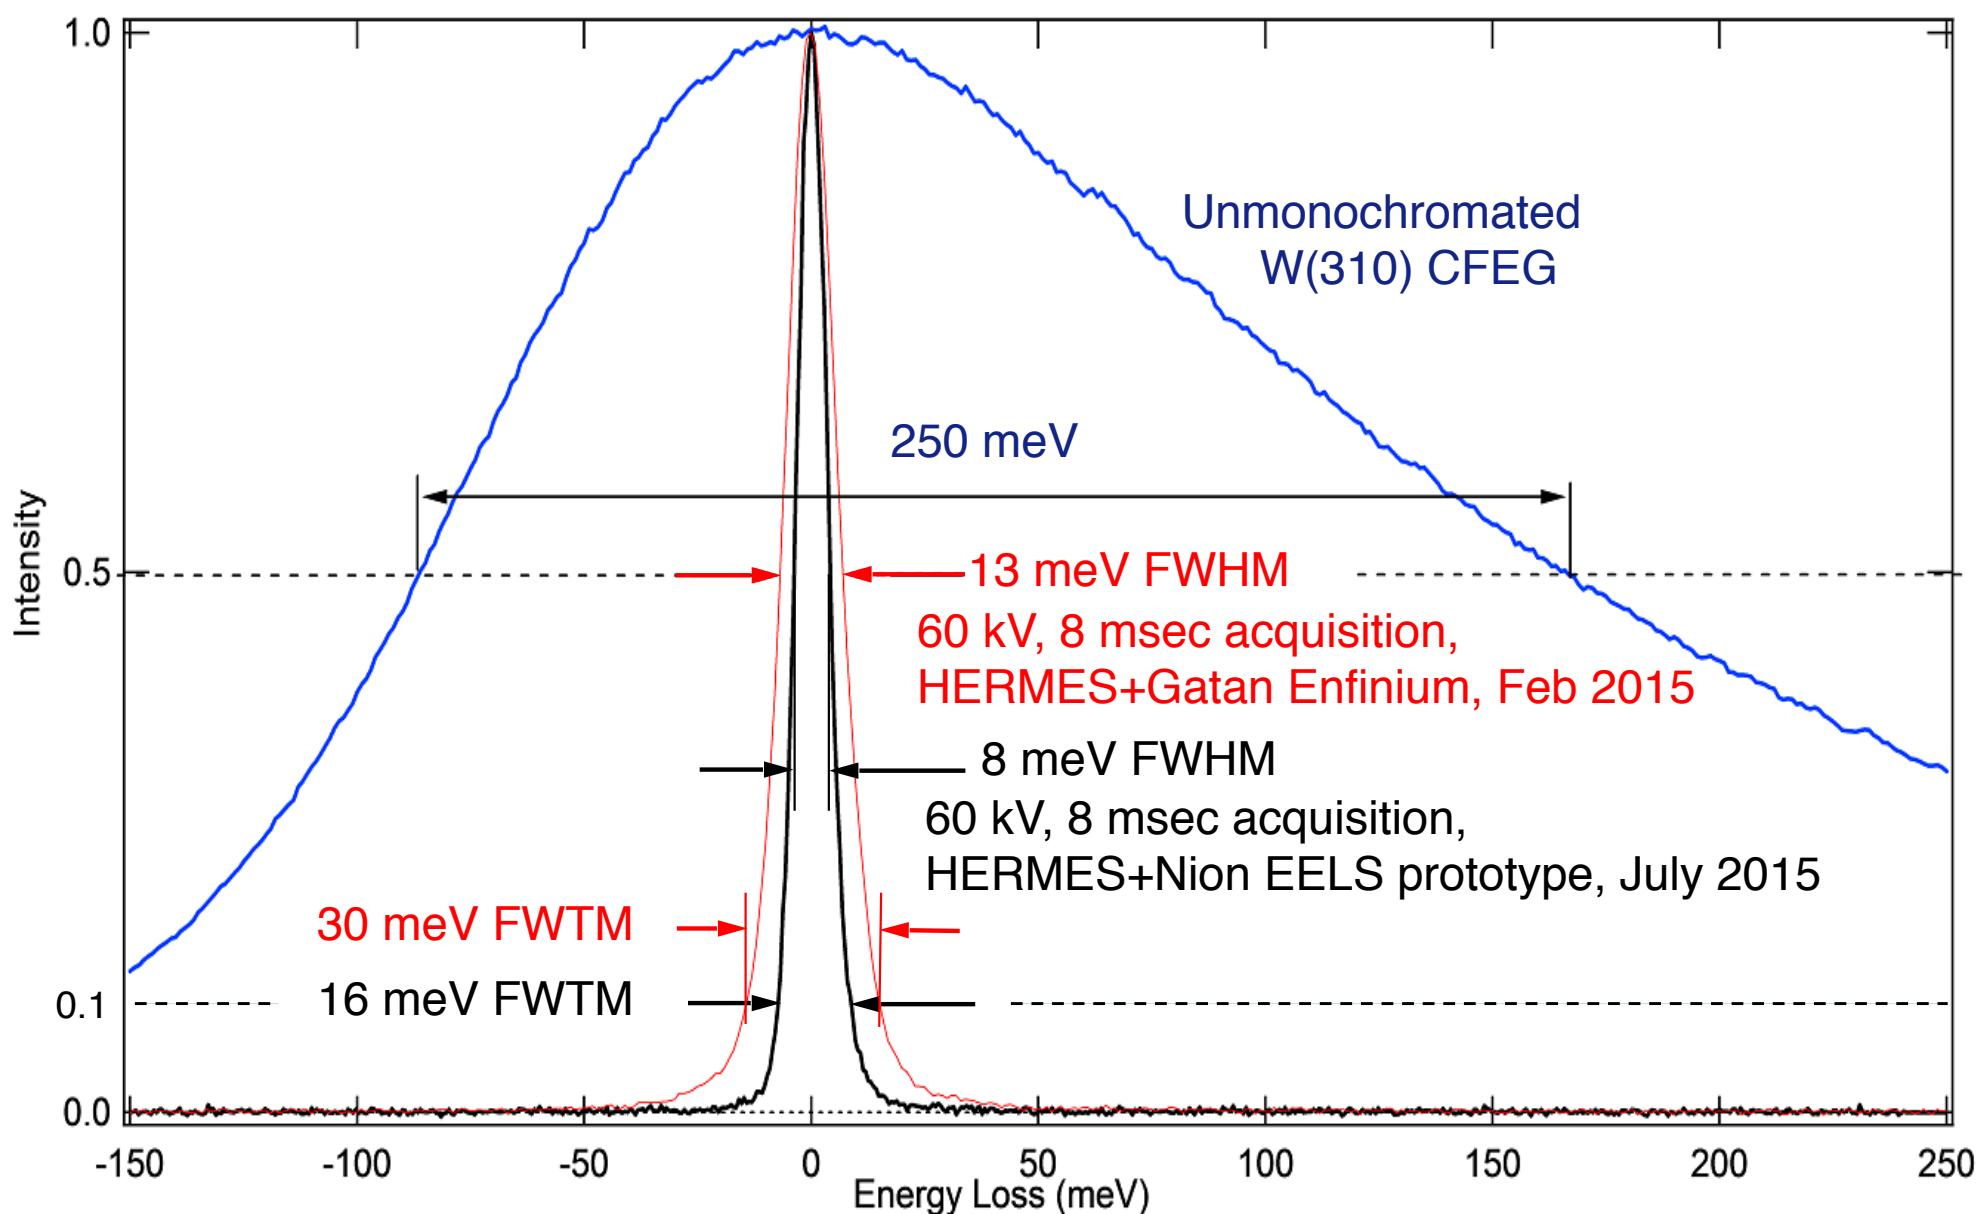

Nion high energy-resolution monochromator

12 meV p-p (3.5 meV rms) $\sim 10^{-7}$

Quantum nano optics in a STEM: light intensity interferometry (HBT)

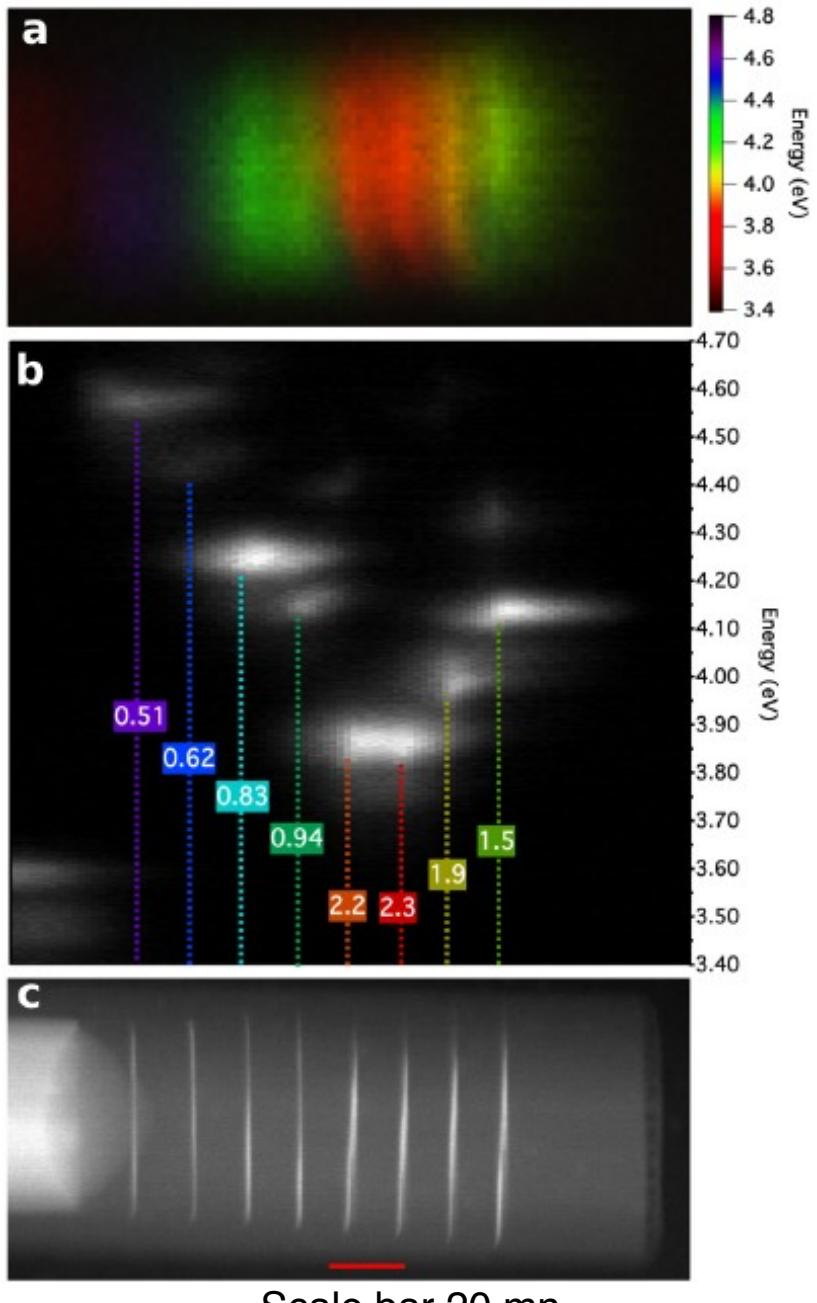

L. H. G. Tizei and M. Kociak,
Phys. Rev. Lett.
110, 153604 (2013).

Exposure time 250s - 300 s
Typical count rate:
30 kcounts/s

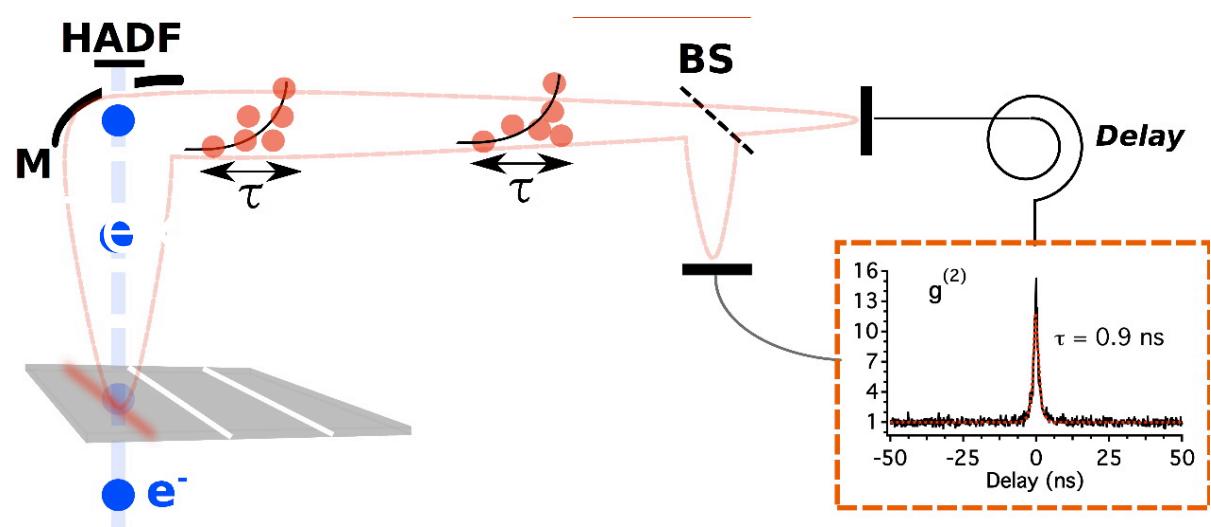

- Optimized CL system with **low excitation** needed, not a single photon can be lost!
- Stealing Quantum Optics knowledge (A. Beveratos et al., Quantum Communication, Computing, and Measurement 3 (2000))

Spatially resolved lifetime measurements in III-N heterostructures

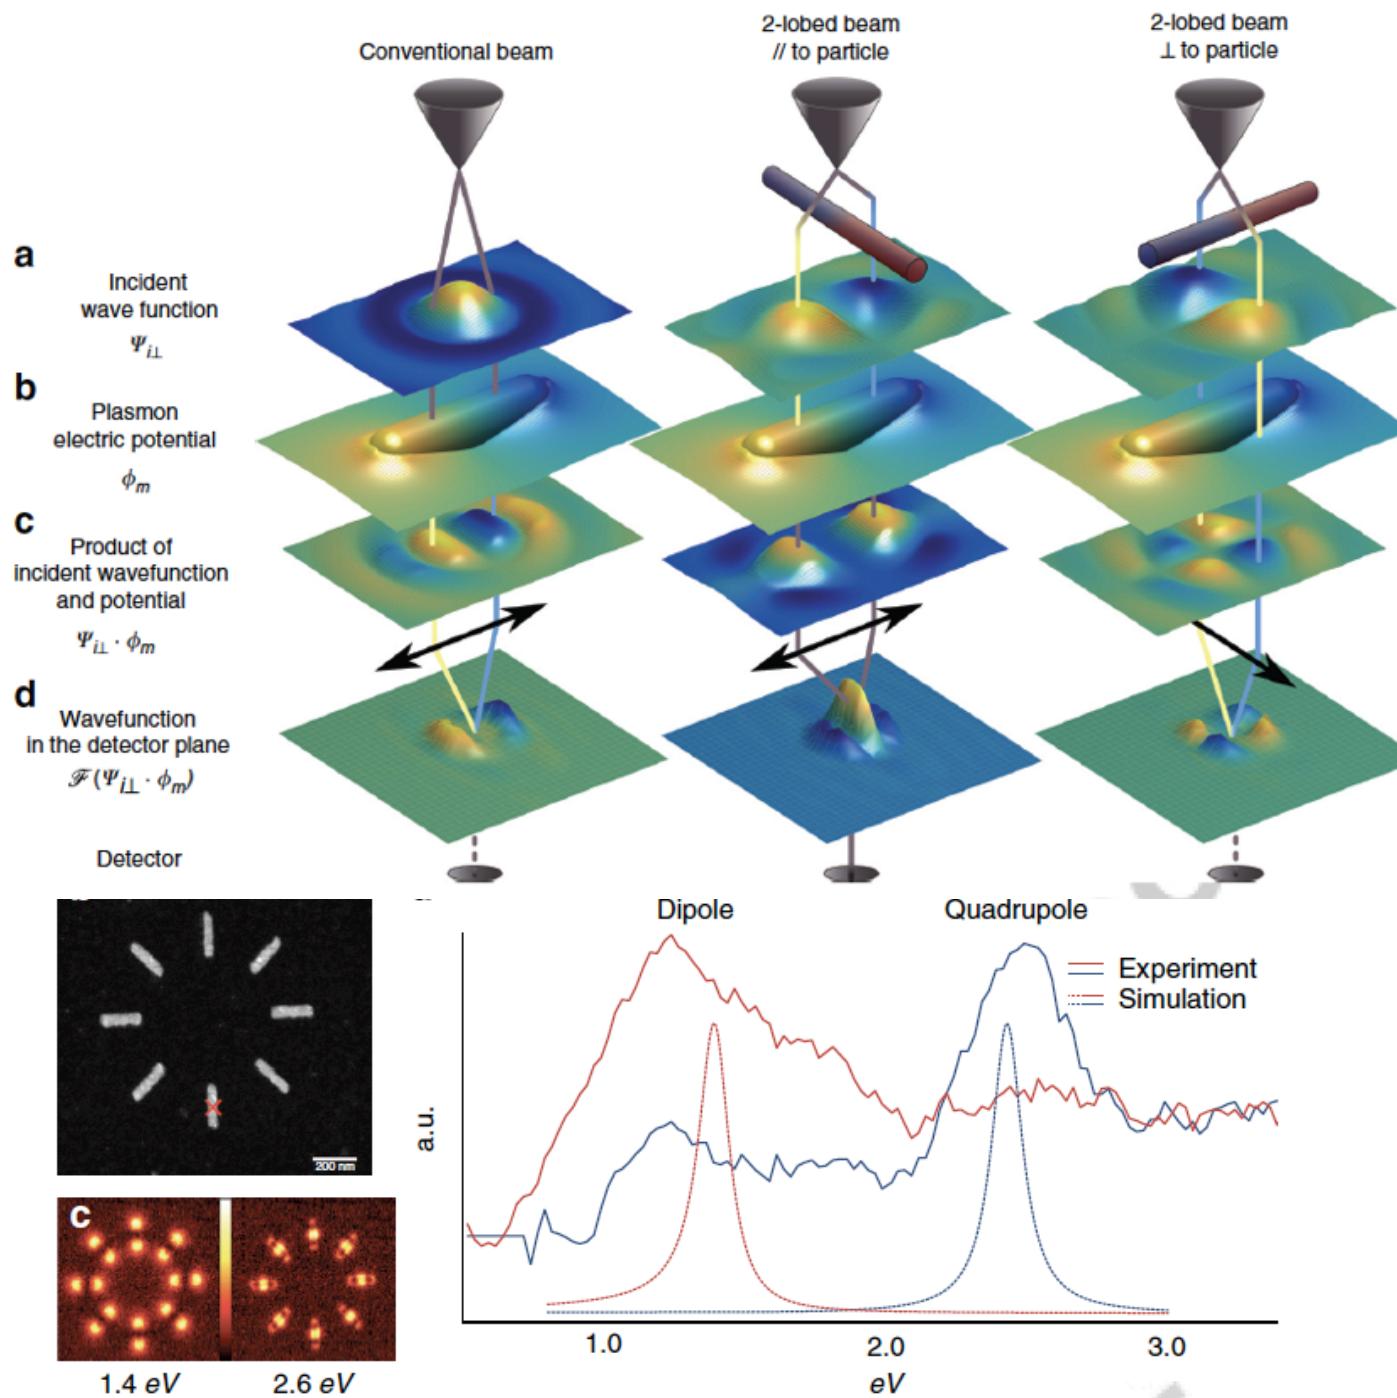

HBT experiments = a nice alternative to time-resolved PL (and CL)

Sub 15 nm ns lifetime measurements
In addition to the spatial resolution, it is fast:
acquisition time tip. 30x faster than PL!

Meuret et al., ACS Photonics (2016)

Manipulating the phase of electron beams

Analogy with optical transitions in atomic physics

Selectively and directionally detect dipolar resonances in a plasmonic nanorod, analogously to what is currently possible with linearly polarized light

Some instrumental perspectives

- | | |
|---|---|
| 1) Probe (in absorption and/or emission) localised plasmons, plasmon polaritons, excitons... | Routine simultaneous acquisition of EELS and CL signals |
| 2) Push downward in the IR regime: map phonons, magnons, ... | Next generation of monochromators, how far can we go in terms of the probed energies? |
| 3) Combine photons and electrons at the nanometer to perform « pump probe » experiments:
Non linear EELS, Electron Energy-Gain Spectroscopy, time-resolved experiments | Pulsed guns, synchronized e-/photon excitation/detection |
| 4) Perform spatially-resolved NRIXS experiments:
probe non-dipolar transitions (d-d and others), tackle modern issues in Condensed Matter Physics | Explore the reciprocal space below 1 eV |

Go to (very) low (controlled) temperatures
